Chapter 1: Python Fundamentals

Lesson 5: Operators and Expressions

---

1. What Are Operators and Expressions?

- **Operators**: Special symbols or keywords in Python that perform operations on one or more operands (values or variables). For example, `+` adds two numbers.
- **Operands**: The values or variables that operators act upon. In `5 + 3`, `5` and `3` are operands.
- **Expressions**: Combinations of operators and operands that Python evaluates to produce a result. For example, `5 + 3` is an expression that evaluates to `8`.

---

2. Types of Operators in Python

A. Arithmetic Operators

These operators perform mathematical operations.

Operator	Description	Example	Result
`+`	Addition	`5 + 3`	`8`
`-`	Subtraction	`5 - 3`	`2`
`*`	Multiplication	`5 * 3`	`15`
`/`	Division (returns float)	`5 / 2`	`2.5`
`//`	Floor Division (integer)	`5 // 2`	`2`
`%`	Modulus (remainder)	`5 % 2`	`1`
`**`	Exponentiation	`2 ** 3`	`8`

Example:

```
a = 10
b = 3
print(a + b)   # 13
print(a / b)   # 3.333...
print(a // b)  # 3
print(a % b)   # 1
print(a ** 2)  # 100
```

B. Comparison (Relational) Operators

These compare two values and return a boolean (`True` or `False`).

Operator	Description	Example	Result
`==`	Equal to	`5 == 5`	`True`
`!=`	Not equal to	`5 != 3`	`True`
`>`	Greater than	`5 > 3`	`True`
`<`	Less than	`5 < 3`	`False`
`>=`	Greater than or equal	`5 >= 5`	`True`
`<=`	Less than or equal	`3 <= 5`	`True`

Example:

```
x = 7
y = 4
print(x > y)   # True
print(x == y)  # False
print(x <= 7)  # True
```

C. Logical Operators

These combine boolean expressions.

Operator	Description	Example	Result
`and`	True if both are True	`True and False`	`False`
`or`	True if at least one is True	`True or False`	`True`
`not`	Inverts the boolean value	`not True`	`False`

Example:

```
a = True
b = False
print(a and b)  # False
print(a or b)   # True
print(not a)    # False
```

D. Assignment Operators

These assign values to variables, often with an operation.

Operator	Description	Example	Equivalent

Operator	Description	Example	Equivalent
`=`	Assign	`x = 5`	`x = 5`
`+=`	Add and assign	`x += 3`	`x = x + 3`
`-=`	Subtract and assign	`x -= 2`	`x = x - 2`
`*=`	Multiply and assign	`x *= 4`	`x = x * 4`
`/=`	Divide and assign	`x /= 2`	`x = x / 2`
`//=`	Floor divide and assign	`x //= 2`	`x = x // 2`
`%=`	Modulus and assign	`x %= 3`	`x = x % 3`
`**=`	Exponent and assign	`x **= 2`	`x = x ** 2`

Example:

```
x = 10
x += 5  # x is now 15
x *= 2  # x is now 30
print(x)  # 30
```

E. Bitwise Operators

These operate on binary representations of integers.

Operator	Description	Example	Result
`&`	Bitwise AND	`5 & 3`	`1`
`|`	Bitwise OR	`5 | 3`	`7`
`^`	Bitwise XOR	`5 ^ 3`	`6`
`~`	Bitwise NOT	`~5`	`-6`
`<<`	Left shift	`5 << 1`	`10`
`>>`	Right shift	`5 >> 1`	`2`

Example:

```
a = 5  # Binary: 0101
b = 3  # Binary: 0011
print(a & b)  # 1 (Binary: 0001)
print(a | b)  # 7 (Binary: 0111)
print(a << 1) # 10 (Binary: 1010)
```

F. Identity Operators

These check if two variables refer to the same object in memory.

Operator	Description	Example	Result
`is`	True if same object	`x is y`	Varies
`is not`	True if different object	`x is not y`	Varies

Example:

```
x = [1, 2, 3]
y = x
z = [1, 2, 3]
print(x is y)     # True (same object)
print(x is z)     # False (different objects)
print(x == z)     # True (same values)
```

G. Membership Operators

These test if a value is in a sequence (like a list, string, or tuple).

Operator	Description	Example	Result
`in`	True if value is found	`3 in [1, 2, 3]`	`True`
`not in`	True if value not found	`4 not in [1, 2, 3]`	`True`

Example:

```
fruits = ["apple", "banana"]
print("apple" in fruits)      # True
print("orange" not in fruits) # True
```

---

3. Operator Precedence

When multiple operators are in an expression, Python follows a precedence order (similar to math's PEMDAS). Here's a simplified list (highest to lowest):

1. `**` (Exponentiation)
2. `~`, `+`, `-` (Unary operators)
3. `*`, `/`, `//`, `%`
4. `+`, `-` (Addition/Subtraction)
5. `<<`, `>>`
6. `&`
7. `^`, `|`

8. Comparison operators (`>`, `<`, `==`, etc.)
9. `not`
10. `and`
11. `or`

Example:

```
result = 5 + 3 * 2  # Multiplication first: 5 + (3 * 2) = 11
print(result)       # 11

result = (5 + 3) * 2  # Parentheses override: (5 + 3) * 2 = 16
print(result)         # 16
```

---

4. Building Expressions

Expressions combine operators and operands. Python evaluates them based on precedence and associativity (left-to-right for most operators, except `**` which is right-to-left).

Examples:

```
# Simple expression
x = 5 + 3 * 2  # 11

# Complex expression
y = (10 / 2) ** 2 + 3 > 15 and 7 % 2 == 1
# Step-by-step:
# 10 / 2 = 5
# 5 ** 2 = 25
# 25 + 3 = 28
# 28 > 15 = True
# 7 % 2 = 1
# 1 == 1 = True
# True and True = True
print(y)  # True
```

---

5. Practical Examples

Let's apply what we've learned:

Example 1: Calculate Area

```
length = 5
width = 3
area = length * width
print(f"Area: {area}")  # Area: 15
```

Example 2: Check Even or Odd

```
num = 10
is_even = num % 2 == 0
print(f"{num} is even: {is_even}")  # 10 is even: True
```

---

6. Exercises for Practice

1. Write an expression to calculate the perimeter of a rectangle.
2. Check if a number is divisible by both 3 and 5.
3. Write a program that:
    - Asks the user to input two numbers.
    - Prints the results of addition, subtraction, multiplication, division, and modulus operations.
4. Write a program that:
    - Asks the user to input a base number.
    - Calculates and prints the result of raising the base to the powers of 1, 2, and 3 using the `**` operator.
5. Write a program that:
    - Asks the user if it's sunny (yes/no) and if it's warm (yes/no).
    - Converts responses to booleans (`True` for "yes", `False` for "no").
    - Uses `and`, `or`, and `not` operators to print:
        - Is it sunny AND warm?
        - Is it sunny OR warm?
        - Is it NOT sunny?
6. Create a program that:
    - Asks the user to input a starting score.
    - Uses assignment operators (`+=`, `-=`, `*=`) to:
        - Add 5 to the score.
        - Subtract 3 from the score.
        - Multiply the score by 2.
    - Prints the score after each operation.
7. Create a program that:
    - Asks the user to input two numbers.
    - Uses comparison operators (`>`, `<`, `==`, `!=`) to check and print whether the first number is greater than, less than, equal to, or not equal to the second.
